
**How Spatial and Transport Planning affects
Car Ownership and Commute Mode Choice**

***Max Bohnet

Hypothesis and Research Questions

- In **car-dependent** areas with a **poor** local & regional **accessibility** by foot, bicycle, and public transport households tend to own **more cars** than in areas, where cars provide only few accessibility advantages.
- How to integrate car ownership into travel demand models in a way that is sensitive to land use and transport policy?
- How to model household car ownership and car use of household members for commute trips?
- Does it make a difference for mode choice effects if one integrates car ownership effects?

Cars per household for a typical 2-adult household

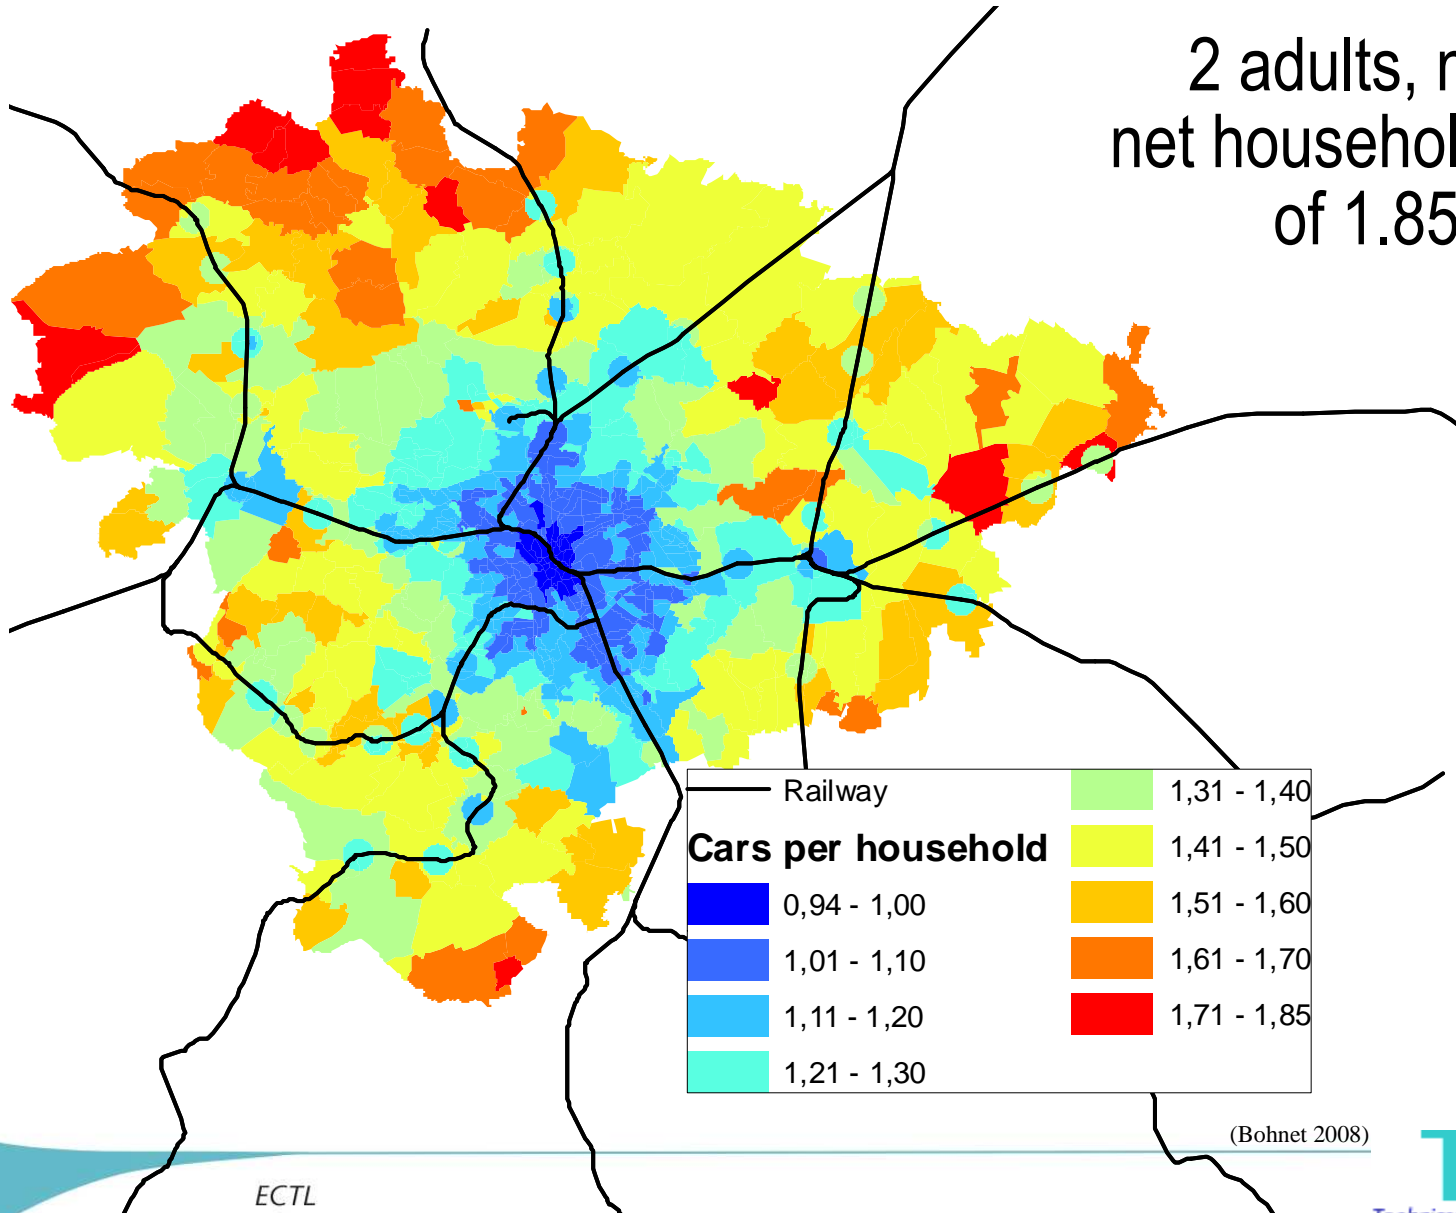

Ordinal Logit Model based on 4.500 household interviews from the Hanover Region

2 adults, no kids net household income of 1.850 €

Cars per household for a typical 2-adult household

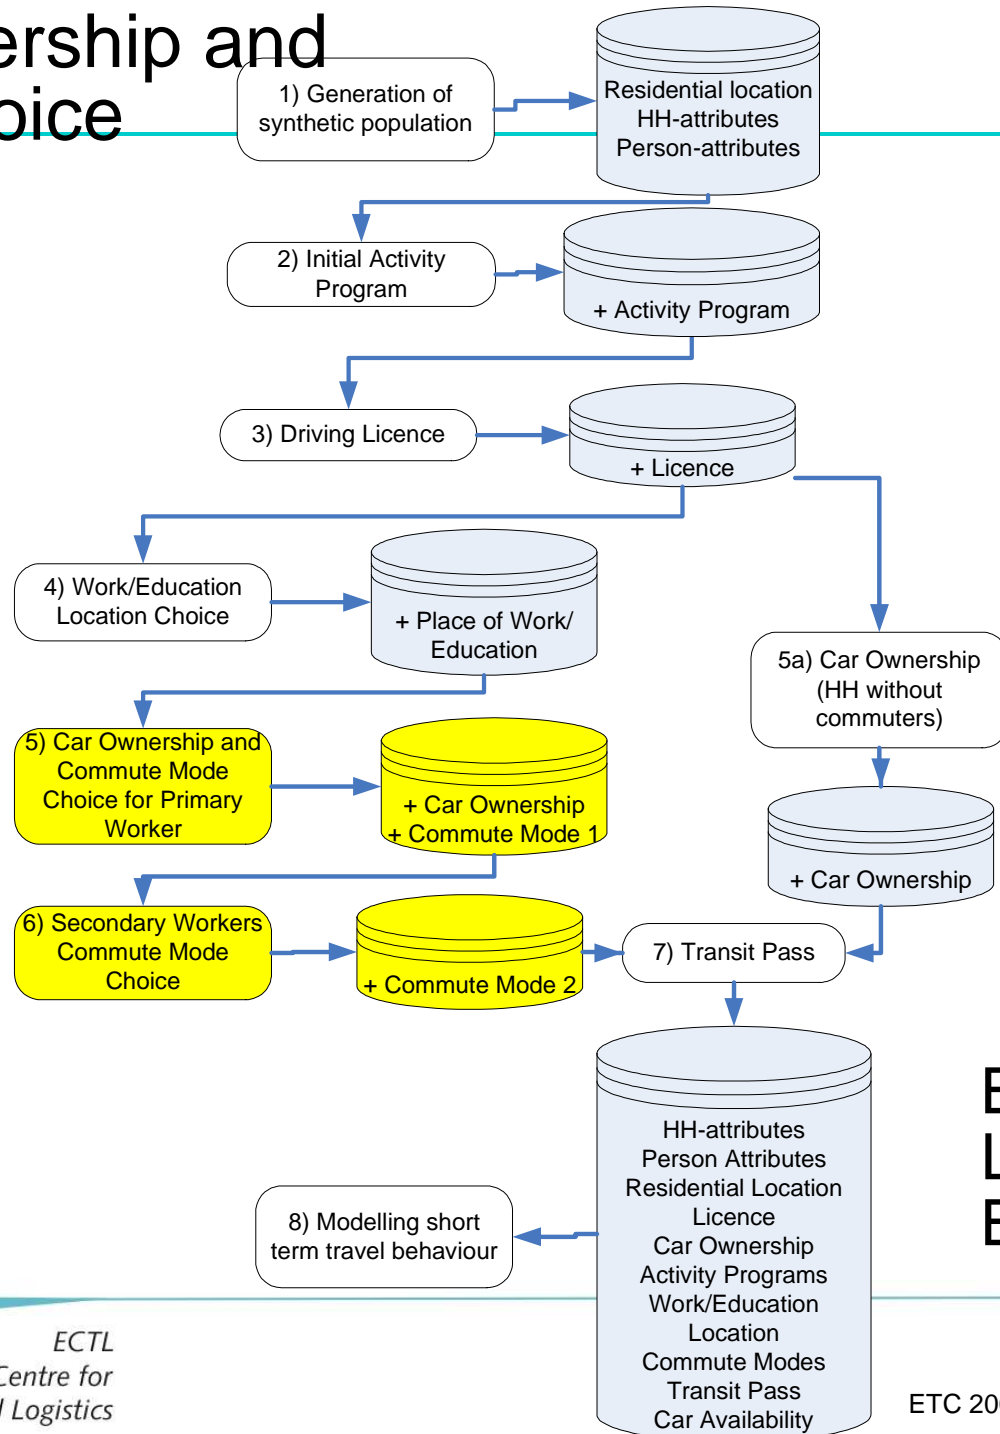

2 adults, no kids
net household income
of 1.850 €

(Bohnet 2008)

Car ownership and mode choice

commute

Car-Ownership/Mode Choice Model

Linking Models through LogSum-Indicators conditional upon Car Availability

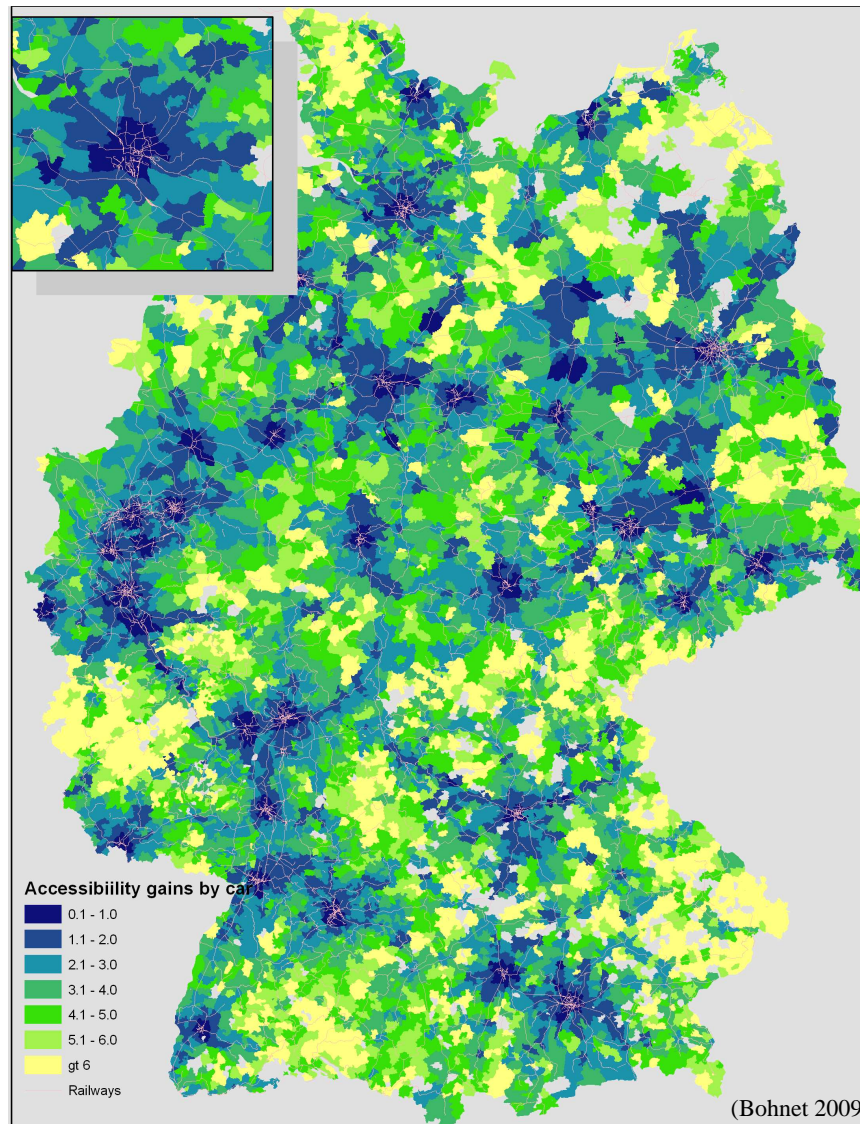

Data Used: The German Socio-Economic Panel

- Multi-purpose household panel survey
- Running since 1984
- 14.000 household interviews from 1998 and 2003 : focus on travel behaviour and environment
- 2003: car ownership and mode choice 5 years ago

- Data includes indicators on residential location type and local accessibility (for shopping...)
- additional regional accessibility indicators on Zip-Code-Level have been added

Accessibility gains by car to next high-level-centre

Accessibility
Indicator:

| In(Remaining income) | | | | |
| | 14,71 | | | |

more licenced drivers
children in household
→ more household cars

more licenced drivers
1st worker takes other mode
accessibility gap without car for
secondary commuters
shopping facilities and mixed
Neighbourhood
→ lower car ownership

higher housing density
→ less cars

poor public transport accessibility of
next middle/high level centre
→ more cars

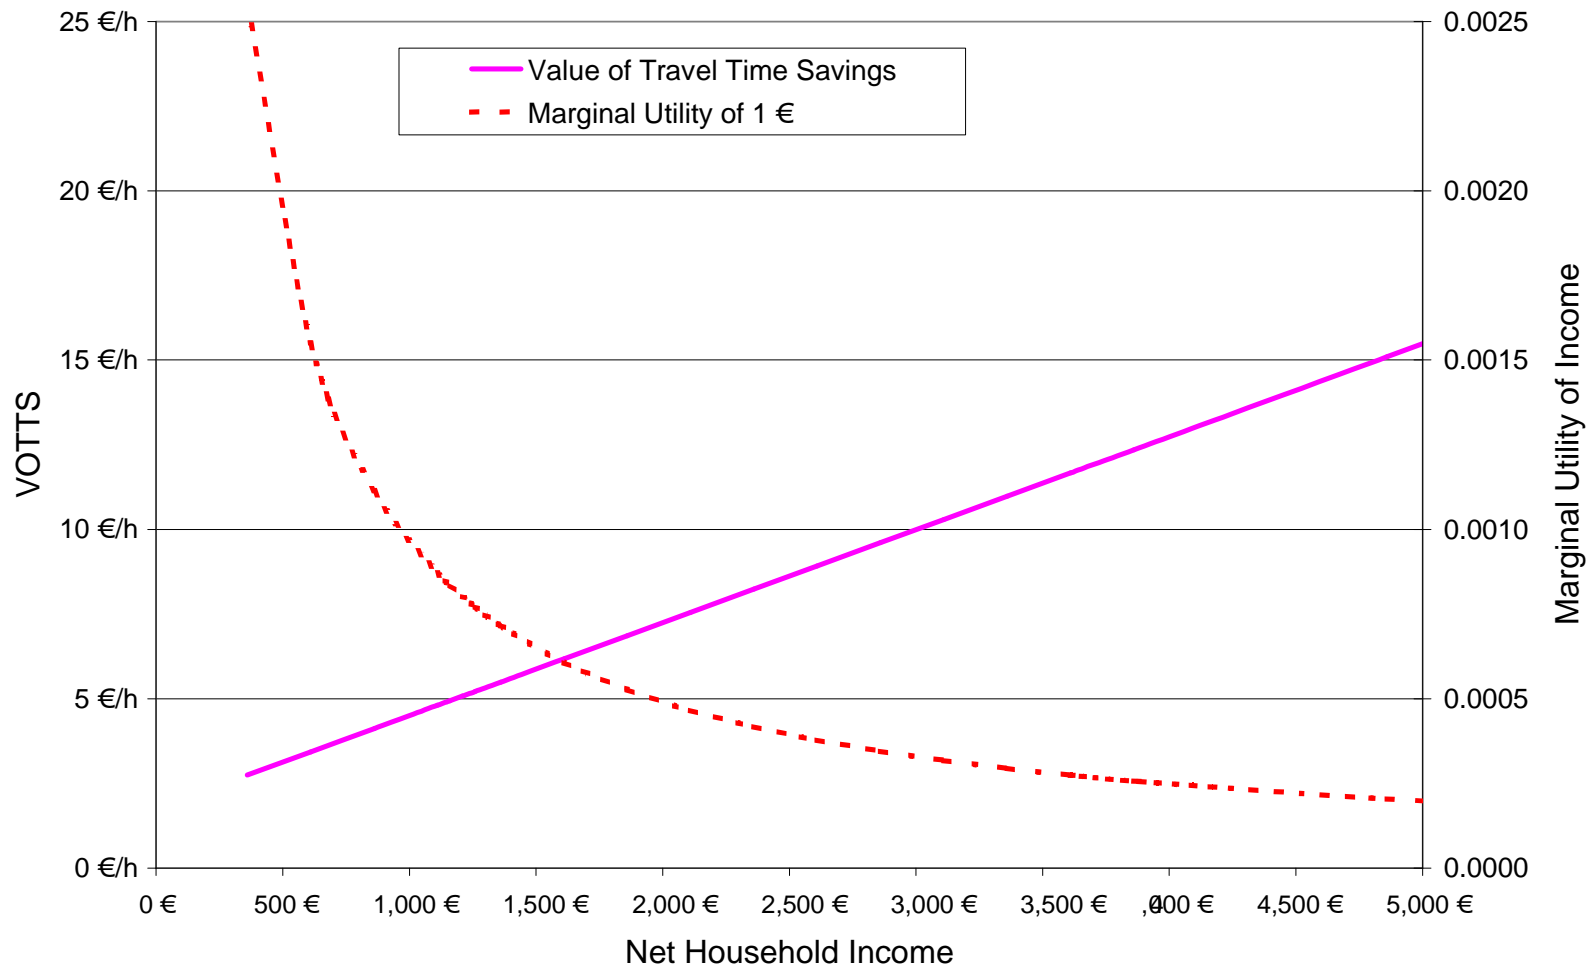

Car ownership 5 years ago
→ habituation to live with/without cars

Marginal utility of remaining income and value of travel time savings

Alternative specific variable: $\ln(\text{remaining income})$

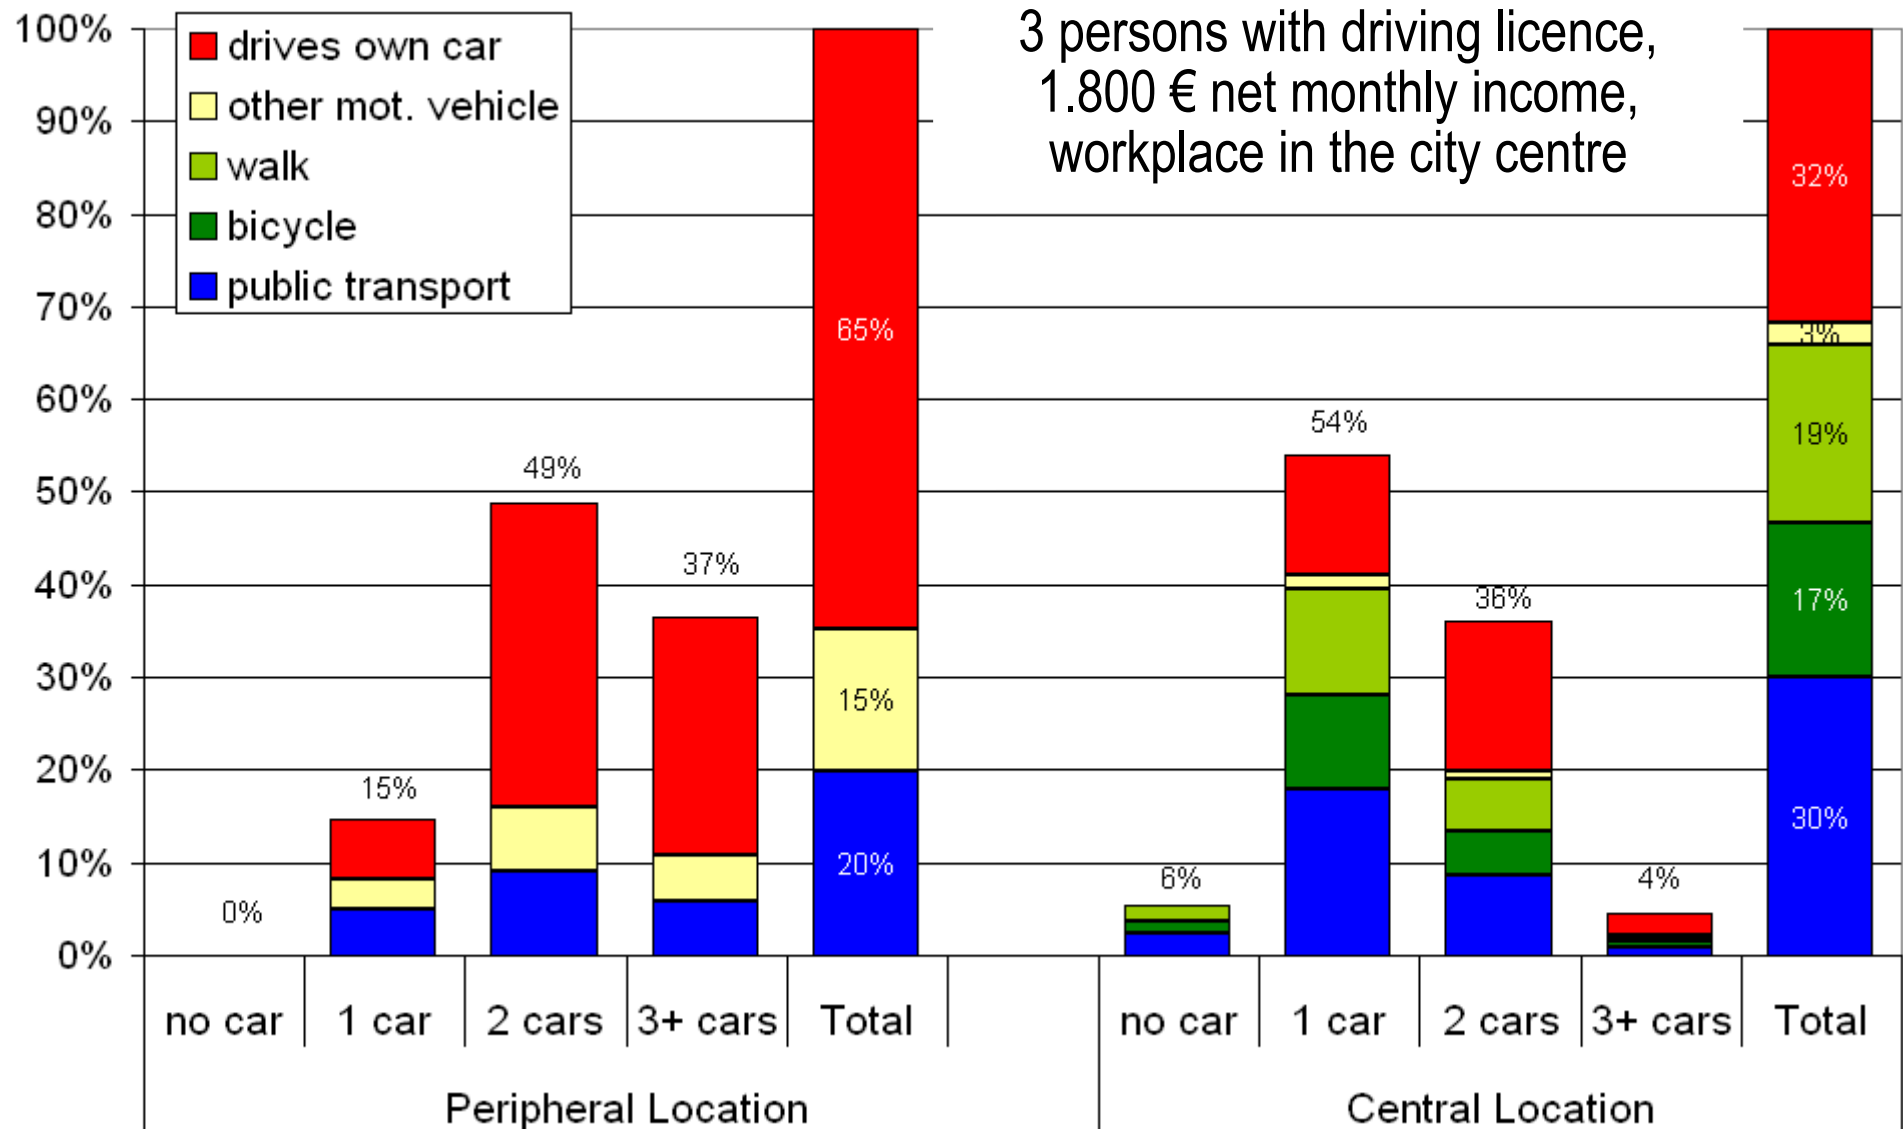

$$= \ln [\text{Remaining Income} - (\# \text{ of cars} * 200 \text{ €}) - \text{variable commute costs} - \text{hh size-factor}]$$

Marginal Utility of Income and Value of Time for 2-Person-Household with 1 car

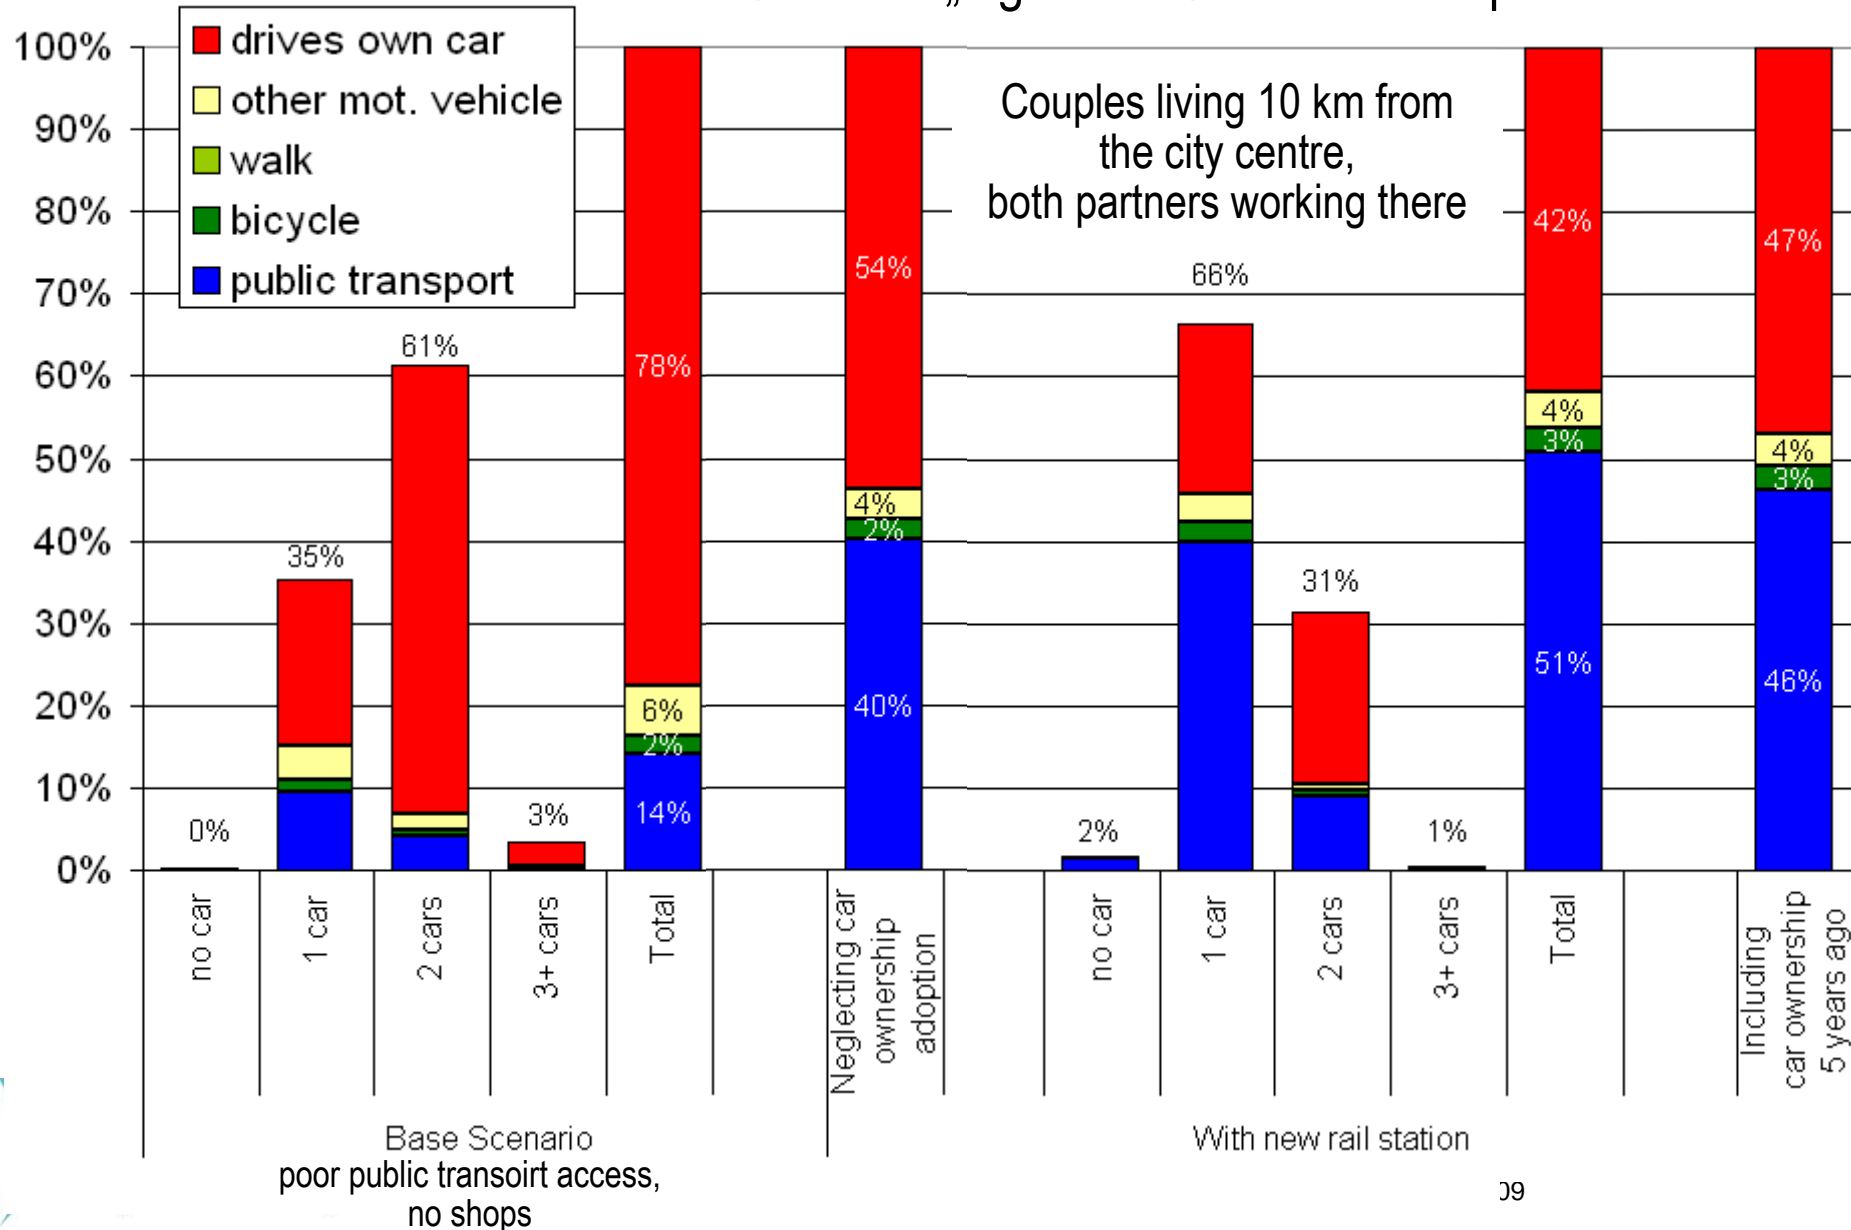

Car ownership and primary workers commute mode choice at different locations

Comparisons for typical household

Impact of "new rail station" scenario on car ownership and primary workers commute mode choice of typical household

Scenario „Light-Rail Station Development“

Conclusions and further research needs

- Urban form and transport services shapes not only mode choice but also household car ownership levels
- Land use and transport policies that improve/sevaguard accessibility by foot, bicycle and public transport might reduce the need for car ownerhsip
- This saves space and money for parking provision
- Neglecting car ownership effects:
underestimation of the effectiveness of land use and transport policy
- however – people get used to car dependent / car free lifestyle – change needs time
- new urban development:
provide shops and public transport from the beginning

Thank you for your attention
